The era of molecular medicine begun after the completion of the Human Genome Project in 2003 (NHGRI). The availability of the database of approximately 3 billion base pairs and 30,000 genes in human DNA has led to a better understanding of physiological and pathological changes in the human body.

Precision Medicine Initiative

“Tonight, I am launching a new Precision Medicine Initiative to bring us closer to curing diseases like cancer and diabetes --- and to give all of us access to the personalized information we need to keep ourselves and our families healthier.”

President Barack Obama, State of the Union Address, January 20, 2015

Precision Medicine

After US President Barack Obama proposed in 2015 the “Precision Medicine Initiative” and provided US $215 million for the program in obtaining the breach of human genome in associated with diseases, the Genome-Wide Association Studies started [1]. GWAS is considered the most powerful available tool to study the association between phenotypes and genotypes and also to identify common low-penetrance susceptibility loci in a particular disease. Each person gave a sample of DNA, from which millions of genetic variants are read using SPN arrays. If one type of variant (one allele) is more frequent in people with the disease, the variant is said to be associated with that disease [2].

Tuberculosis

Tuberculosis is an infectious disease generally caused by inhaling *Mycobacterium tuberculosis* that occur to anyone at any age and all over the world, but only about 10% individuals are at a higher risk of acquiring the disease than others [3]. Approximately 90% of those infected with *Mtbb* have asymptomatic, latent TB infection, with only a 10% lifetime chance of progression to clinically active TB. Those are particular groups of individuals being at a higher risk of acquiring the disease than others, including individuals with insufficient or suppressed immune systems, i.e., infants, foreign-born individuals in TB prevalent countries, HIV/AIDS patients, diabetics, alcoholics, long-standing users of immune-suppressed drugs, e.g. corticosteroids, people live in poor sanitation and crowded countries such as formerly in South and South-East Asia Regions, and others.

Formerly, tuberculosis was prevented, as well as diagnosed and treated by circumstantial and clinical means. Such achievements depends largely on variable potentiality of attention and ambiguity of human responsible, which left of a good number of remaining infective sources. In the present era of advanced genomic technology, medical practice is adapting to comprehensive “precision medicine”, but occur the question “will precision medicine ever be possible to lead to the control of tuberculosis?” [4]

In responding to such a question, one must intimately understand the molecular basis of tuberculosis and its causative organism that mostly is *Mycobacterium tuberculosis* (*MTB*) [5]. On believing that through a genetic approach to finding genes and genetic variations such as the diversity of genetic susceptibility to diseases in human populations would verify the molecular mechanisms of tuberculosis pathogenesis.
Unfortunately, our extensive literature review of available reports indicated that most hypothesis-free efforts to revamp the idea of TB genetic susceptibility have not identified candidate genes playing an important role in active tuberculosis. Nevertheless, the hope remains from a few findings cited at the followings, although controversies remained, should be mentioned.

(2) The linkage locus at chr2q35 contains a candidate gene SLCL11A1. The gene associated with TB is a solute carrier family 11 member 1 gene (SLCL11A1) at Chr2q35, which is the natural resistance-associated macrophage protein 1 gene (NRAMP1); the genetic effect is absolutely unrelated to DTH response (Forget A, et al. Infect Immun 1981; 32: 42-47).

(3) NRAMP1 is a proton acting as a divalent-metal efflux pump at the phagosomal membrane of macrophage; it depletes divalent metal as Zn\(^{2+}\), Cu\(^{2+}\), Fe\(^{2+}\) and Mn\(^{2+}\) from bacteria-containing phagosomes. Deletion of these divalent metals may render the MTB more sensitive to the killing by oxygen radicals (Forbes JR, et al. Trends Microbiol 2001; 9: 397-403).

(4) A number of studies have reported the genetic association of HLA class II polymorphisms with TB susceptibility. The DQbeta1Asp57 allele was associated with increased risk of progressive pulmonary tuberculosis. The DQbeta1Asp57 demonstrates reduced ability to bind to the immunogenic peptides of MTB, which may weaken the Th1 response. (Delgado JC, et al. J Immunol 2006; 176:1090-7).

(7) Toll-like receptors (TLRs) play an essential role in the activation of innate immunity against microbial infection (Takeda K, et al. Semin Immunol 2004; 16: 3-9). Davila S, et al. identified the TB association of the TLR7 and TLR8 locus in Indonesian cohort. This study highlights the potential function of the TLRs in anti TB immunity (PLOs Genet 2008; 4:e1000218; PubMed: 18927625)

(10) Identification of a novel association tagged by a single-nucleotide polymorphism (SNP) rs4331426 at 18q11.2. (Thye T, et al. Nat Genet 2010; 42(9):739-41 )

Addendum

Diagnosis

Diagnosis of tuberculosis nowadays can be made by a molecular test which detects the DNA in TB bacteria. It uses a sputum sample and gives result in less than two hours; Or by a urine test for detecting glycan antigen lipoarabinomannan (LAM), a marker of active TB [6]. Both provide broad implications for pulmonary TB scanning and early treatment [5,7].

TB Vaccine

BCG vaccine has been in practice for preventing primary TB infection for almost a century (97 years). A new generation of vaccines intended to suppress the transition from infection to disease on person already infected (tuberculin-positive persons) [8,9]. Presumably they already have implants containing dormant bacilli.

Conclusion

At this point, the role of precision medicine has not been accomplished in the arena of tuberculosis practice. Although certain genetic risk loci at the positions 11p13 and 18q11 have been reported and a possibility that there would be in the near future new generation vaccines likes that of Lowrie DB, et al. available for use to suppress the transition from infection to disease in tuberculin-positive persons [10].
